Two examples about EM algorithm

2026-04-28

R Experiment

(I like to use R; Python can be used in the same way.)

Suppose $X \sim N(\mu, 1)$, where μ is unknown.

The observable data are $\{0, 2, x\}$, where x indicates the missing value.

We can use the following EM algorithm to find $\hat{\mu}$

```
mu <- 2   ## Initial value
tol <- 1e-6  ## Difference between mu_new and mu
diff <- Inf  ## set some very large value as initial difference

while (diff > tol) { ## If difference is greater than some very small value, then stop
  mu_new <- (0 + 2 + mu) / 3
  diff <- abs(mu_new - mu)
  mu <- mu_new
  print(mu)
}
```

```
## [1] 1.333333
## [1] 1.111111
## [1] 1.037037
## [1] 1.012346
## [1] 1.004115
## [1] 1.001372
## [1] 1.000457
## [1] 1.000152
## [1] 1.000051
## [1] 1.000017
## [1] 1.000006
## [1] 1.000002
## [1] 1.000001
## [1] 1
```

Because:

1. Loglikelihood of $\{0, 2, x\}$: $logL(\mu|x) \propto -\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + (x-\mu)^2\}$, where we omit all the constants.
2. $E_{X|\mu'}[logL(\mu|X)]$
   $\propto E_{X|\mu'}[-\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + (X-\mu)^2\}]$
   $= -\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + E_{X|\mu'}[(X-\mu)^2]\}$
   $= -\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + E_{X|\mu'}[X^2 - 2X\mu + \mu^2]\}$
   $= -\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + E_{X|\mu'}[X^2] - 2E_{X|\mu'}[X]\mu + \mu^2]\}$

$$= -\frac{1}{2}\{(0-\mu)^2 + (2-\mu)^2 + (1+\mu'^2) - 2\mu'\mu + \mu^2]\}$$

3. Maximum $E_{X|\mu'}[logL(\mu|X)] \Rightarrow \mu = \dfrac{0+2+\mu'}{3}$
4. Set an initial value for μ' and derive μ until $\mu = \mu'$

Gaussian Mixture Model

Suppose we observed some scores from 2 groups (e.g. $N(\mu_1, \sigma_1^2), N(\mu_2, \sigma_2^2)$). However we could not observe the group variable.

Data look like this

```
y <- c(-0.39, 0.12, 0.94, 1.67, 1.76, 2.44, 3.72, 4.28, 4.92, 5.53,
       0.06, 0.48, 1.01, 1.68, 1.80, 3.25, 4.12, 4.60, 5.28, 6.22)

hist(y) ## this is the histogram (empirical distribution) of data
```

Suppose Z_i is the latent group variable (unobservable), where $P(Z_i = 0) = 1 - \pi, P(Z_1 = 1) = 1 - \pi$.

$Y_i|Z_i = 0 \sim N(\mu_1, \sigma_1^2) = \phi(\mu_1, \sigma_1|y_i); Y_i|Z_i = 1 \sim N(\mu_2, \sigma_2^2) = \phi(\mu_2, \sigma_2|y_i)$

Then the marginal pdf of Y: $f_Y(y) = (1-\pi)\phi(y|\mu_1, \sigma_1) + \pi\phi(y|\mu_2, \sigma_2)$

Likelihood function is

$L(\pi, \mu_1, \sigma_1, \mu_2, \sigma_2) = \prod_{i=1}^{N}(1-\pi)\phi(\mu_1, \sigma_1|y_i) + \pi\phi(\mu_2, \sigma_2|y_i)$

We could use MLE to estimate the parameters $(\pi, \mu_1, \sigma_1, \mu_2, \sigma_2)$ but the derivation is complicated.

Consider the EM algorithm.

```
## EM
par <- c(0.5, 0.5, 1, 0.5, 1)  # Initial values of (pi, mu1, mu2, sigma1, sigma2)
```

```r
tol <- 1e-6
diff <- Inf  ## set some very large value as initial difference

while (diff > tol) { ## If difference is greater than some very small value, then stop

  pi <- par[1]
  mu1 <- par[2]
  mu2 <- par[3]
  sigma1 <- par[4]
  sigma2 <- par[5]

  ## ---- E-step ----
  f1 <- dnorm(y, mu1, sigma1)
  f2 <- dnorm(y, mu2, sigma2)

  gamma <- pi * f2 / ((1 - pi) * f1 + pi * f2)

  ## ---- M-step ----
  pi_new <- mean(gamma)

  mu1_new <- sum((1 - gamma) * y) / sum(1 - gamma)
  mu2_new <- sum(gamma * y) / sum(gamma)

  sigma1_new <- sqrt(sum((1 - gamma) * (y - mu1_new)^2) / sum(1 - gamma))
  sigma2_new <- sqrt(sum(gamma * (y - mu2_new)^2) / sum(gamma))

  par_new <- c(pi_new, mu1_new, mu2_new, sigma1_new, sigma2_new)

  diff <- max(abs(par_new - par))
  par <- par_new

  print(par)
}
```
